

Project Development Phase

Model Performance Test

Date	01 /10/26
Team ID	SWTID-2026-2467
Project Name	Auto Ticket Classification using Flow Designer
Maximum Marks	

Model Performance Testing:

This project uses ServiceNow Flow Designer rule-based ticket classification. The implementation does not train or fine-tune a machine-learning model. Therefore, the evidence below reports the actual classification configuration and rule-validation evidence instead of inventing ML training or validation percentages.

S.No.	Parameter	Values	Screenshot
1	Model Summary	Rule-based ticket classification implemented using ServiceNow Flow Designer. The flow is triggered when an Incident Workflow record is created with Category blank, evaluates the ticket condition/short description, and uses conditional branches followed by Update Record actions.	 Flow Designer trigger, conditions and Update Record actions
2	Accuracy	Training Accuracy: Not used in this implementation because no ML model is trained. Validation Accuracy: Not used because no ML validation dataset is used. Rule-configuration validation: 4 configured classification mappings are present: Wi-Fi → Network, Projector → Hardware, Forgot Password → Access, Slow Computer → Performance.	 Configured classification mappings and dependent values
3	Fine Tuning Result (if Done)	ML fine-tuning is not part of this implementation. The implemented rule configuration was refined by making Subcategory dependent on Category and configuring the four category-to-subcategory mappings. This provides the rule-based classification structure used by the flow.	 Subcategory dependent-field configuration
